Lab 1 Activity

Lab Activity

- 1. Read "NY_Temp.txt" into R as shown in Lab 1.
- 2. Use a function to find the descriptive statistics including IQR for the windspeed variable, Wind.
- 3. Make a basic index plot (scatterplot of Windspeed according to Case Number).
- **4.** Add a linear regression line and a quadratic regression line to the index plot. Which line describes the trend more appropriately in your opinion?
- **5.** Create a 1D-scatterplot of Wind.
- **6.** Choose and create one graph to help you evaluate normality (histogram, boxplot, Q-Q plot, or kernal density plot).

Some R Practice

1. The rep() function can be used to repeat objects:

```
# we define vectors with the `c()` function

vec <- c(2, 3)
vec

## [1] 2 3

# can you spot the difference between the `times = ` and `each = ` argument?

rep(vec, times = 3)

## [1] 2 3 2 3 2 3

rep(vec, each = 3)

## [1] 2 2 2 3 3 3</pre>
```

Task

• Repeat the vector c(-1,3,-5,7,-9) twice, with each element repeated 3 times, and store the result. Display the result sorted from largest to smallest (use the sort() function; run help(sort) for the help page of the sort() function).

2.

Task

- If I have a vector with 5 elements, I use the rep() function to repeat each element 4 times, and then I repeat the resulting vector 3 times, how long is the final vector?
- **3.** Let's look at some common R objects and how to subset them:

vectors (1-Dimensional):

```
x <- c(2,1,5,6, 17)
# element 3 is extracted like so
x[3]</pre>
```

[1] 5

```
# elements 1 and 3 can be extracted like so
x[c(1,3)]
## [1] 2 5
# elements can be dropped by using the "-" sign
# to drop the elements 2 and 4
x[-c(2,4)]
## [1] 2 5 17
matrices (2-Dimensional):
# many ways to define matrices
# a quick way is to use the `cbind()` of `rbind()` functions
# `cbind()` glues together 1D vectors as columns
# `rbind()` glues together 1D vectors as rows
# for example we create a matrix we 3 rows and 4 columns
mat \leftarrow rbind(c(4,2,5, 8),
             c(14,78,6, 38),
             c(33,7,10, 326))
# to extract the element in the second row and the fourth column, we run
mat[2, 4]
## [1] 38
# so for 2D objects, [Row, Column]
# to get the second column
mat[,2]
## [1] 2 78 7
lists (1-Dimensional):
```

```
# lists can store any type of object
# to create a list
list_1 <- list(x, mat)</pre>
# to extract elements from a list we use [[]]
# so to extract the second element
list_1[[2]]
        [,1] [,2] [,3] [,4]
##
## [1,]
           4
                2
                      5
                           8
## [2,]
          14
               78
                      6
                          38
## [3,]
          33
                7
                    10 326
# we can also name list elements
list_names <- list("vector" = x,</pre>
                    "matrix" = mat)
# now we can also use the `$` operator to access named elements
list_names$matrix
##
        [,1] [,2] [,3] [,4]
## [1,]
           4
                      5
## [2,]
          14
               78
                      6
                          38
## [3,]
          33
                7
                    10 326
# the [[]] method still works just fine
list_names[[2]]
        [,1] [,2] [,3] [,4]
## [1,]
           4
                2
                      5
## [2,]
          14
               78
                      6
                          38
## [3,]
        33
                    10 326
```

Tasks

• If you create a new vector y that contains the first to the fourth element of x and the third row of the mat object, what will be the length of y?

- Create y as specified above. Print y.
- Extract the second and fifth elements of the "vector" element inside the list_names object in a single line of code
- assign NA to the element in the third row and second column of the "matrix" element inside the list_names object in a single line of code. (hint: you will need to use the <- operator). Print the "matrix" element inside the list_names object to confirm.
